

Contributions to the knowledge of the Lepidoptera of Vlăsia Plain (Muntenia, Romania)

Valeriu ALBU & Sebastian ALBU

Summary: This study presents the results of an investigation carried out between 1966 and 2013, aiming to record the lepidoptera fauna of the Vlăsia Plain, a region centered on Bucureşti, Romania, and part of the more extensive Valahia Plain. 1251 lepidoptera representing 458 species were collected from forests, steppes, marshy areas and hilly zones situated between Bucureşti and the border of the Carpathian foothills. From these collections, 33 previously unrecorded species were added to the Valahia Plain checklist. Isolated populations of several species previously considered extinct from the area or with a doubtful occurrence, were re-discovered and re-confirmed in wooded habitats near Bucureşti (*Lopinga achine* and *Ancylis upupana*), on the hills at Târgovişte (*Zerynthia polyxena*) and in forest clearings around the city of Piteşti (*Brintesia circe*).

Key words: Lepidoptera biodiversity, European butterflies and moths, Balkan invertebrate fauna, lepidoptera of Romania

Introduction

The study of the lepidoptera fauna of the Vlăsia Plain (part of larger Muntenia) began in the late 19th century, mainly with the recording of the butterflies and macromoths collected in and around Bucureşti, the country's capital city (CARADJA 1895, FLECK 1900). Gradually, interest shifted to also include micromoth populations in studies by CARADJA (1901), POPESCU (1938), and POPESCU-GORJ (1964). These laid the groundwork for the current knowledge of the lepidoptera fauna of Bucureşti and its surroundings. Unfortunately, this activity came to a halt in the mid-1960s and was not resumed until the late 1990s, with the work of SZÉKELY (1998, 2002, and 2011). The present study, which primarily documents species collected from 1979 to 1982, attempts to fill this 30-year gap in the monitoring of lepidoptera populations of Bucureşti and its surroundings.

Material and methods

The lepidoptera surveying activities reported in this paper extend over a period of 47 years, from 1966 to 2013. During this time, we investigated 19 sites in four counties situated on the Vlăsia Plain (Ilfov, Dâmboviţa, Argeş, and Giurgiu). Table 1 lists these sites and their altitudes along with the number of specimens and species recorded at each of them. Collection sites included electrically illuminated structures, forests, and village gardens in Ilfov,

illuminated structures and pastures in Dâmboviţa, wooded areas and clearings in Argeş, and a marshy area in Giurgiu.

We sampled for lepidoptera during the entire flight season, from March to November. Specimens were collected by sweeping vegetation with a standard insect net. Larval specimens were reared to adulthood either on the plants on which they were found or on alternative food sources, e.g. dandelion (*Taraxacum officinalis*), plantain (*Plantago major*), or willow leaves (*Salix* spp.). Pupae found on rare occasions were retained until eclosion. Sampling events occurred throughout the year, temperature and precipitation permitting.

We followed the species arrangement proposed in „The Lepidoptera of Europe- A Distributional Checklist” (KARSHOLT and RAZOWSKI 1996), with the amendments contained in „Revised higher classification of the Noctuoidea” (LAFONTAINE and FIBIGER 2006) and in Fauna Europaea Web Service v.2.6 (KARSHOLT and NIEUKERKEN 2013). The „Catalogue of the Lepidoptera of Rumania” (RÁKOSY et al. 2003) was used as a benchmark for the species known to occur in our study area.

Results

We recorded 458 lepidoptera species out of a total of 1251 individuals collected during the entire time span of the study. Of these, 412 species (89.9%) and 1156 specimens (92.5%) were obtained in the four-

Table 1. Sampling sites by county with their respective species and specimen numbers, arranged by increasing altitudes. Many species were caught in two or more counties, which accounts for the higher county species sum (584) than the total species collected (458).

County	Site	Altitude	Number of species	Number of specimens
Giurgiu	Călugăreni	58 m	85 (14.6%)	140 (11.2%)

year interval between 1979 to 1982. We recorded the most species from Ilfov (362), followed by Dâmbovița (103), Giurgiu (85), and Argeș (34), as detailed in Table 1. Many species were collected in two or more counties. These species represent 21 suprafamilies, as shown in Table 2. The Noctuoidea and Geometroidea had the highest numbers of species in our sample with 134 and 96, followed by Papilioidea and Pyraloidea with 66 and 49, respectively. At the bottom were Eriocranioidea, Hepialoidea, Tischerioidea, Choreutoidea, and Thyridoidea with one species for each. We recorded lepidoptera activity from March to December, with the most species collected during May and June (Fig. 1). This graph shows a steep increase in species abundance from March to June, followed by a decrease in July, another small peak in August, and a gradual decrease in abundance from September to December. The only month devoid of any records was January. In February 1983 we had a *Saturnia pavonia* (LINNAEUS, 1758) pupa hatch indoors and in December 1980 and 1981 we collected single specimens of *Agonopterix alstromeriana* (CLERCK, 1759) and *Erannis defoliaria* (CLERCK, 1759), respectively.

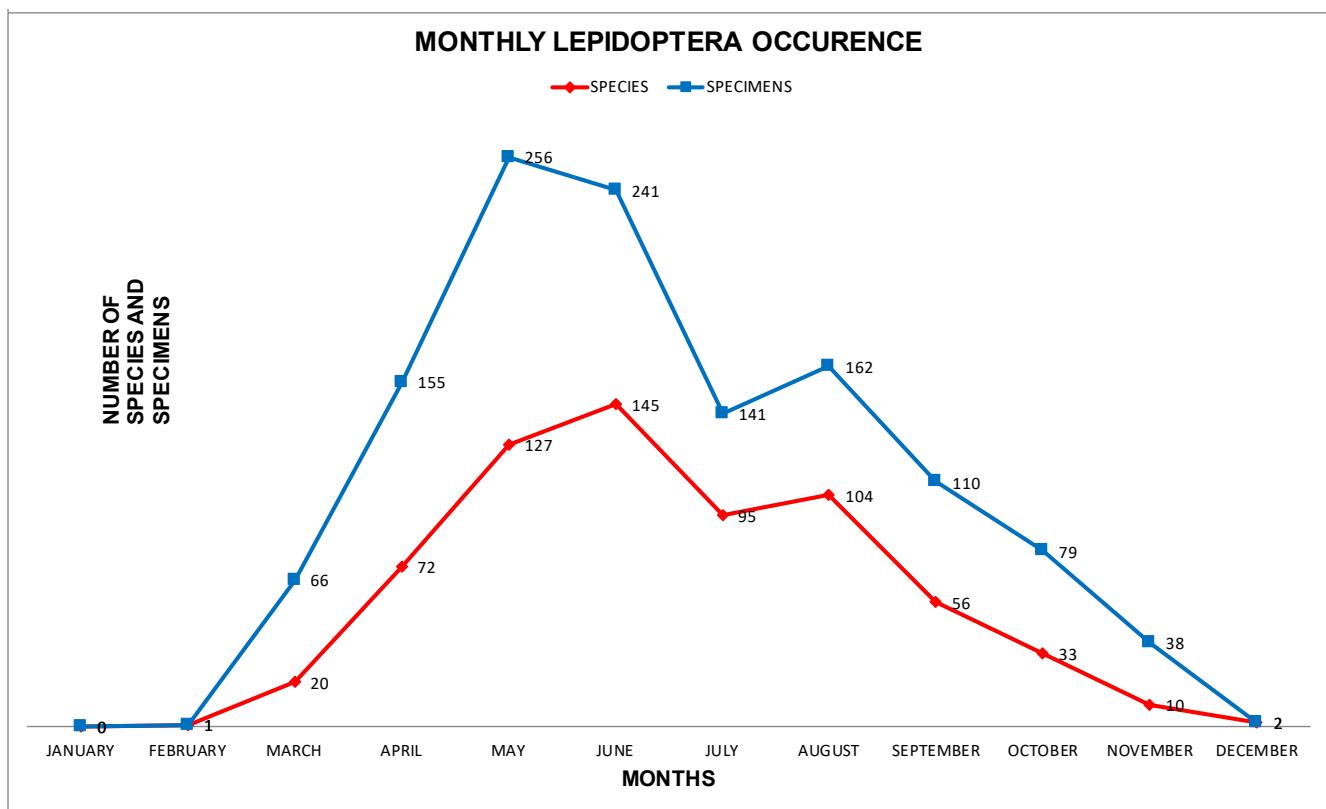

Fig. 1. Line graph depicting monthly differences in numbers of lepidoptera species and specimens collected during this study. Many species were caught in more than one month, resulting in a higher monthly sum (665) than the total species number for the study (458).

Discussion

During this study, we recorded 458 lepidoptera species from the Vlăsia plain. Of these, 421 were species known to regularly occur in the area, while 33 were previously unrecorded from here, as well as from Muntenia (Table 3). Four more species were encountered in places from where they were considered extirpated. We rediscovered *Ancylis upupana* (TREITSCHKE, 1835) in Andronache forest in 1982. The last record of this species from Muntenia was prior to 1900 (RÁKOSY *et al.* 2003). We encountered several populations of *Lopinga achine* (SCOPOLI, 1763) in Mogoșoaia and Andronache forests near București in 1981 and 1982 and of *Zerynthia polyxena* (DENIS and SCHIFFERMÜLLER, 1775) in the foothills at Mănăstirea Dealu near Târgoviște in 1982. These two species had not been seen from these areas since the beginning of the 20th century and were considered extinct from here (POPESCU-GORJ 1964, RÁKOSY 2013). There are a few even more recent records of *L. achine* from 1997 to 2004 reported from this area by SZÉKELY (2011) and at least one more record of *Z. polyxena* from Târgoviște in 1987 (personal observation). We documented the occurrence of *Brintesia circe* (FABRICIUS, 1775) in Argeș, a species which had a questionable presence in the area (RÁKOSY 2013). This suggests the presence and persistence of these species in Muntenia, most likely as localized and isolated populations.

Our data suggest that the most and least annual

lepidoptera flight activity occurred in June (145 species) and January (0 species), respectively. The monthly species abundance curve (Fig. 1) shows an increase in lepidoptera flight activity from March to June and a decrease from September to December, similar to that observed in the study of the lepidoptera of București (ALBU and ALBU 2016). We observed sporadic activity in December, as shown by the records of *A. alstromeriana* and *E. defoliaria* in (1980 and 1981, respectively). The former species overwinters as adult, while the latter flies in the late fall, making a December detection not unusual, given the occasional occurrence of warm days during this month. The February record of a *S. pavonia* adult hatching indoors is also consistent with personal observations of wild individuals of this species flying in March and April.

RÁKOSY *et al.* (2003) compiled a list of 1916 lepidoptera species from the existing literature and museum collections representing the fauna of the entire Muntenia region, thus also covering our study area. Adding the 458 species from this study to the 78 non-duplicated species that we encountered by surveying an urban park in București during approximately the same period (ALBU and ALBU 2016), we arrive at 536 lepidoptera species recorded from the Vlăsia plain in the latter part of the 20th century. This represents 28% of the total of 1916 species found by RÁKOSY (2003). Some species, including *Noctua haywardi* (TAMS, 1926) were recorded just recently in this area

∞ Table 3. Newly recorded lepidoptera species from Muntenia. K & R refers to the KARSHOLT and RAZOWSKI (1996) checklist.

(SZÉKELY 2002), while others such as *Saturnia spini* (DENIS and SCHIFFERMÜLLER, 1775) disappeared from the region in the 20th century (RÁKOSY *et al.* 2003). The disappearance of species should be considered with caution, however. After many years of lacking records, our collections of *L. achine*, *Z. polyxena*, and *A. upupana* show how increased sampling can reveal the presence of species considered extinct from an area.

According to the Romanian lepidoptera catalogue (RÁKOSY *et al.* 2003), there are 2453 „Microlepidoptera” (pre-Lasiocampoid) and 1507 „Macrolepidoptera” (post-Lasiocampoid) species sensu KARSHOLT and RAZOWSKI (1996) known to occur in Romania. Of these, 874 „Microlepidoptera” and 1042 „Macrolepidoptera” species (35% and 69%, respectively) are known from Muntenia. For comparison, there are 1708 „Microlepidoptera” and 1277 „Macrolepidoptera” species (69% and 84%, respectively) listed from Transylvania and 1414 „Microlepidoptera” and 1192 „Macrolepidoptera” species (57% and 79% respectively) from Moldova, both regions comparable in size and relief to Muntenia. This makes the „Microlepidoptera” fauna of Muntenia one of the least known of Romania. Even allowing for the extensive losses in various habitats to urbanization and agriculture, we posit a higher lepidoptera species richness (especially „Microlepidoptera”) for Muntenia than what the records suggest. This underscores the importance of carrying out additional surveys, especially investigating the „Microlepidoptera” fauna, to gain a better understanding of its composition and of the population and species shifts that are occurring in this area.

Acknowledgements

We would like to express our gratitude to Jean-François LANDRY for his help in identifying the Coleophoridae and Scythrididae and to Cees GIELIS for clarifying the identity of the Pterophoridae species encountered during this study. We extend our thanks to Alexander ALBU for reviewing this manuscript.
