3. Assistant Professor, Department of Education, Allameh Tabatabaei University, Tehran, Iran.

### Article history:

Received date: 2022/11/08 Review date: 2022/12/25 Accepted date: 2023/01/08

Keywords: Curriculum, Brain-based, Interaction, Motivation **Purpose**: The purpose of the present research is to present a brain-based curriculum model focusing on interaction and motivation in the secondary school.

**Methodology**: In order to achieve this goal, qualitative approach, field method and semi-structured in-depth interview techniques were used. The study population included prominent curriculum planning experts, researchers and faculty members and 15 people were interviewed based on the data saturation.

The data collection tools included texts and semi-structured interviews, and the method of data analysis also included inductive thematic analysis (Attride-Stirling thematic networks).

Findings: The results of the research showed that the curriculum design components included four dimensions: goals, content, teaching methods, and assessment methods, which affect students' interaction and motivation. Goals included indices of changing mental images, real learning environment, flexibility of brain-based curriculum, information storage during learning. Content included indices of development of brain ability, mechanism of brain function, cognitive learning, content understanding, triggering body and brain activity, teaching methods including practical learning, learning in the environment, cooperation in class activity, different learning style, getting students to take responsibility for learning, effectiveness of education, purposeful and conscious teaching, continuous information processing. Assessment method included self- assessment, understand the content easily, flexible learning, encouraging activities. The interaction included indices of sharing new experiences in learning; improving the brain ability; and discussing different topics. Stimulation of learning and motivation included the indices cognitive function of the brain, challenging and enjoyable learning. Conclusion: The results showed that the brain-based curriculum emphasizes on goals, content, teaching and assessment methods, which is designed with an emphasis on interaction and motivation.

### 1. Introduction

Curriculum, as the basic subsystem of higher education, is strongly influenced by the policies adopted by higher education and in turn affects higher education and its functions (Jafari et al., 2019). When defining the curriculum as a field of study, theorists consider curriculum as a field that has specific dimensions, topics, conceptual scope or content structure like any other scientific field. Various theoreticians seek to determine the thematic and conceptual limits and gaps in the field of curriculum studies (Rudi et al., 2017). Galin believes that the curriculum should focus on a set of mental skills; activities such as self-exploration, attention, concentration, visualization; mental-physical exercises; art-enhanced visualization activities (Ozizi, 2017).

Knowing the brain mechanism during learning has important effects on education. Considering the brain mechanism, the nature of learning and the way information and skills are stored and retrieved, and then using this knowledge in curriculum design can ensure peak learning for all people with different individual characteristics. (Badiei et al., 2020).

Basically, there are many scientific and practical methods and approaches to teach and improve the quality of students' learning; for example, group learning, learner-based learning, experiential learning; however, there have been few studies on the approach that can be used in all fields of education. The new educational approach called the service learning approach has been used in most scientific fields and at different educational levels (Marandi et al., 2018). Brain-based learning has been proposed since 1980 as a new approach in teaching and understanding the path that the brain naturally designs for learning (Hassani et al., 2015).

Brain-based learning means that as long as the brain can continue to function, its processes are normal and learning can occur (Morgan, 2019). Brain-based learning actually consists of learning based on the methods that the human brain is inherently designed for (Badiei et al., 2020). Therefore, brain-based learning is learning in accordance with the way the brain is naturally designed to learn (Sesmiarni et al., 2020). Brain-based learning (BBL) is one of these theories that has attracted the attention of many education experts. By emphasizing the brain and its mechanism and relating it to learning processes, this theory has brought new topics into the educational field (Shaughnessy, 2016).

Motivation is one of the most important and powerful sources of impulse that affects the behavior of learners and determines the strength and stability of a behavior. Motivation empowers the learner to achieve the goal and acquire the ability to perform necessary activities under certain conditions. Motivation is a complex concept with different dimensions. It is the process by which goal-oriented activities are energized, directed and maintained. The motivation level is different depending on people's thoughts, beliefs and emotions (Nemati et al., 2018). Motivation refers to the internal states of a living being that initiates, guides, and maintains goal-oriented behaviors. In other words, motivation can be defined as a driver and a guiding factor for human activities (Abedi & Rostami, 2017). Academic motivation refers to behaviors that lead to learning and achievement. Academic motivation is an internal process that stimulates activities and continues with the aim of achieving specific academic achievements (Memarian et al., 2015).

Interaction is a kind of action that occurs as two or more objects have an effect upon one another. The idea of a two-way effect, as opposed to a usual one-way effect, is in the heart of the interaction concept. The combination of many simple interactions leads to the emergence of surprising phenomena (Chang & Su, 2020). Based on brain research, collaborative groups can be used in learning environments. These groups make members feel valued in the process of internal interaction, and the brain releases endorphins and dopamine to make people enjoy their work (Sadraei, 2019). Recent results on the brain mechanism in the learning process have led to a new insights on topics such as motivation and interaction. BBL does not function in isolation, but in interaction with others. On the other hand, motivation is the process by which goal-oriented activity is triggered and maintained. In fact, the cognition-motivation interaction is considered as a principle of brain cognitive function (Dadashzadeh et al., 2020).

In a relevant study titled "The relationship between students' awareness of brain-based learning strategies with active memory and creativity", Abassi & Saadipour (2020) showed a positive and significant relationship

between students' awareness of brain-based learning strategies with active memory and creativity. Saber & Dadashi (2019) conducted a study titled "The effect of brain-based learning on the attention and academic self-regulation of sixth grade female students of Ghaemshahr". The results showed that brain-based learning training has a significant effect on the attention and academic self-regulation of sixth grade female students in Ghaemshahr city. Chavoshan Torghabeh (2019) conducted a research titled " The effects of brain-based learning on motivation to learn and academic progress of female students in Jagharegh village". The results indicated that brain-based learning had a significant and significant effect on students' motivation to learn and also on their academic progress.

Sesmiarni et al. (2020) have conducted a study titled "Brain-based learning from the perspective of students". The results of this study showed that.... Hsu (2020) conducted a study titled "Third-grade elementary teachers' understanding of brain-based learning by gender." They found that the brain learning of the female teacher is effective on the gender of the third-grade elementary teacher.

Many previous BBL studies have paid less attention to the understanding of BBL mechanisms, and basically, the learning processes and the type of student-teacher interaction have received less attention in these studies (Dadashzadeh et al., 2020). Therefore, the current research fills this theoretical gap because, on the one hand, it emphasizes BBL processes, and on the other hand, it is based on better student interaction after BBL or participation. Therefore, the purpose of the present study was to determine the components and present the brain-based curriculum model focusing on interaction and motivation in the secondary school.

## 2. Methodology

This is a qualitative (mixed-method) study with a thematic approach. The exploratory-sequential strategy and the inductive thematic analysis (attride-stirling thematic networks) have been used. In this method, first, the basic topics (codes and key points of the text) related to the brain-based curriculum with the focus on interaction and motivation were extracted from the relevant texts, and interviews were also conducted. Then the organizing topics (the topics obtained from the combination and summarization of the basic topics) were determined, and then the comprehensive topics (higher topics that include the principles governing the text as a whole) are extracted, the network of topics belonging to the brain-based curriculum components was compiled and the relevant model was presented.

In this research, to conduct related interviews first, a list of experts in based-based curriculum focusing on interaction and motivation was prepared during the August and September of 2021. To perform interviews, first a general description of the interview regarding based-based curriculum focusing on interaction and the motivation was given, and further explanations were avoided due to the possibility of the risk of bias. After the first interview, all the interviewee's statements were re-read and the related topics were first coded, using Atlas Ti software and audio files. Then the second interview was conducted and the topics related to the previous codes were separated and new codes were assigned to the new topics. ..., the primary codes with similar topics in terms of meaning and content were classified.

The participants included curriculum planning experts, prominent researchers and university faculty members. Professors and researchers who have published BBL research projects were selected as the study participants. To determine this group of experts, the purposeful sampling method was used, and 15 people were considered as interviewees. Library and field (interview) methods were used to collect data.

Validity and reliability of the data were confirmed by the supervisor, advisors and three curriculum planning PHD students. For the member-checking, the results of interview analysis and classification were given to five interviewees that were later confirmed by them. Figure 1 shows the types of questions asked during interviews.

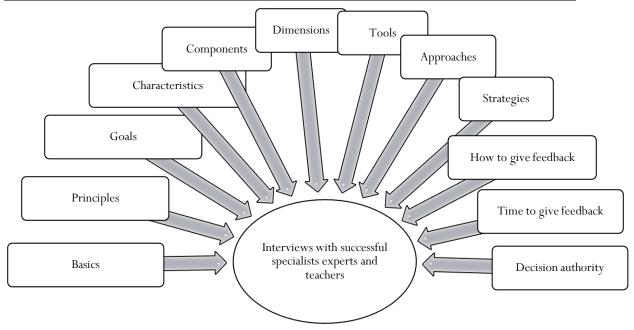

Figure 1: Twelve areas of the qualitative phase interview

The characteristics of the documents are given in Table 1.

Content analysis was used to analyze the research data. Data analysis was carried out using SPSS and LISREL.

# 3. Findings

The frequency of interviewees by gender, age, marital status and level of education is shown in Table 2. Participants were male in more than 66.66% of cases. There were also over 40 and under 25 years of age in more than 46.67% and only 20% of cases, respectively. The interviewees were also married in 80% of cases. They also had MA and BA in more than 46.67% and 20% of cases, respectively.

Table 2: Frequency of interviewees by gender, age, marital status and level of education

Var	riable	Frequency	Percent
	Female	5	33.33
Gender	Male	10	67.66
	Total	15	100
	Under 35 years	3	20
Age	Between 35 and 45 years	5	33.33
C	Over 45 years old	7	46.67
	Total	15	100
	Single	3	20
Marital status	Married	12	80
	Total	15	100
	B.A.	3	20
Level of education	M.A.	7	67.46
Level of education	P.H.D	5	33.33
	Total	15	100

Qualitative content analysis has been used in order to extract brain-based curriculum components focusing on interaction and motivation. Both manifest and latent content analysis methods were used in the present study; in other words, the latent content was also interpreted in some cases. Overall, the following steps were implemented when using the content analysis method:

1. Implementation of interviews: The recorded interviews were implemented in the format of Word software.

2. Data summarization: The results from each interview were summarized and coded in the form of Atlas TI software tables.

3. Data classification: The results from each interview were inserted in a separate table. Such a general table was completed for codes assigned to concepts. Categories are formed when describing the subcategories. The

open codes included 56 indices, which were categorized into 56 open codes, 29 axial codes, and 6 selective codes according to their meaning similarity and category (Table 3).

The indices and factors affecting the brain-based curriculum can be categorized as follows (Figure 2). To categorize concepts, higher levels are placed as categories and lower level concepts are placed as subcategories. Categories are formed by the way the subcategories are described. The open codes identified through the interview include 56 indices, which were categorized into 56 open codes, 29 axial codes, and 6 selective codes according to the semantic affinity and their similar category.

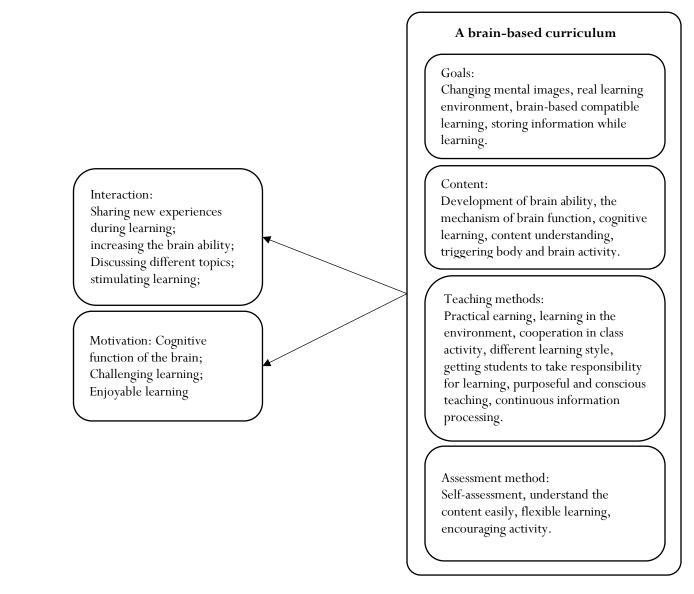

Figure 2: Research analysis model (source: research results)

# 4. Conclusion

According to the results of the present research, the curriculum design components included four dimensions: goals, content, teaching methods, and assessment methods, which affect students' interaction and motivation. Goals included indices of changing mental images, real learning environment and Brain-based compatible learning and information storage during learning. Content included indices of development of brain ability, mechanism of brain function, cognitive learning Content understanding involvement of body and brain activity. Teaching methods also included indices of practical learning, learning in the environment,

cooperation in class activity, different learning style, getting students to take responsibility for learning, effectiveness of education, purposeful and conscious teaching, continuous information processing. The assessment method included indices of including self-assessment, understand the content easily, flexible learning, encouraging activity. The interaction also included indices of sharing new experiences in learning; increase the brain ability; discussing different topics. Stimulation of learning and motivation included indices of the cognitive function of the brain, challenging and enjoyable learning. Each of these indices has its own components.

The goals include indices (change of mental images, real learning environment, brain-based compatible learning, storage of information during learning), which are consistent with the studies by Afrakhteh et al. (2019) Nozohouri Pahrabad (2019), Alkateb (2020), Sesmiarni et al. (2020), and Koushar & Badir (2020). The content includes indices (development of brain ability, the basis of brain function, cognitive learning, content understanding, involvement of body and brain activity), which are consistent with the studies by Afrakhteh et al. (2019) Nozohouri Pahrabad (2019), Alkateb (2020), Sesmiarni et al. (2020), and Koushar & Badir (2020). Teaching methods include indices of (practical learning, learning in the environment, cooperation in class activities, different learning styles, getting students to take responsibility for learning, effectiveness of education, purposeful and conscious teaching, continuous information processing), , which are consistent with the studies by Afrakhteh et al. (2019) Nozohouri Pahrabad (2019), Alkateb (2020), Sesmiarni et al. (2020), and Koushar & Badir (2020). The assessment method includes indices of (selfassessment, understand the learning easily, flexible learning, encouraging activities), which are consistent with the studies by Afrakhteh et al. (2019) Nozohouri Pahrabad (2019), Alkateb (2020), Sesmiarni et al. (2020), and Koushar & Badir (2020). Interaction includes indices (sharing new experiences in learning; increasing brain power; discussing different topics; stimulating learning), which are consistent with the studies by Afrakhteh et al. (2019) Nozohouri Pahrabad (2019), Alkateb (2020), Sesmiarni et al. (2020), and Koushar & Badir (2020), which is consistent with the research by Bakhurst (2008).

To understand the role of the brain-based curriculum focusing on interaction and motivation, one of the effective and important strategies is the curriculum-based learning technique. This is the basic assumption that the curriculum-based learning approach and cognitive neuroscience as well as other experimental learning methods help the student to have a better understanding of the course material. Certainly what one experiences through performance is remembered more than what is merely read, heard or taught. Besides, the application of cognitive neuroscience in education increases social responsibility, moral progress, altruism, competence and scientific knowledge of learners in societies. Brain-based learning approach helps the student to achieve a better understanding of the needs of society and this is different from verbal questions that have a specific answer. The brain-based curriculum approach allows investigating and understanding the society, and thus helps the student know the physical and social environment and understand the real needs and demands of the society, the values and beliefs of the society and all kinds of social facilities and provide a suitable solution with the help of his teacher. The conceptual model of the research is shown in Figure 2.

Knowing the brain mechanism during learning has important effects on education. Knowing the brain mechanism, the nature of learning and how to information and skills are stored and retrieved in the mind, and then using this knowledge in curriculum design can ensure maximum learning for all people, with different individual characteristics. Each brain has unique characteristics. This uniqueness implies that each person needs a different educational experience; however, these differences are not recognized in our culture and most students are placed within an educational system and only the needs of people with a dominant left hemisphere are met. Our educational system is basically dedicated to people with a dominant left hemisphere.

#### Acknowledgements

The author would like to express his gratitude to Dr. Vasefian and Dr. Mazbouhi and other professors.
