31 **Abstract**

32 **Background:** Crocodile farming aims to produce high-quality skins from captive
33 crocodilians. Captivity usually exposes the animals to stressful conditions, resulting in
34 increased serum corticosterone (CORT) levels that correlate negatively with those of sex
35 hormones and reproductive success. **Objective:** To evaluate serum concentrations of CORT
36 and sex hormones and their relationship in farmed Morelet's crocodiles (*Crocodylus*
37 *moreletii*), in the non-breeding (NBS) and breeding (BS) seasons. **Methods:** The study
38 included 59 adult crocodiles (29 females, 30 males). One blood sample was collected in
39 NBS (n = 31) and BS (n = 28) from each crocodile to determine serum concentrations of
40 CORT, estradiol (E₂), progesterone (P₄), and testosterone (T). Throughout the study,
41 crocodiles were kept in mixed-sex groups and were fed once or twice a week. **Results:** In
42 females, CORT was higher (p<0.05) in NBS, but had no correlation (p>0.05) with E₂ or P₄
43 in any season. In males, CORT was similar (p>0.05) in NBS and BS, and had no correlation
44 (p>0.5) with T. **Conclusion:** Levels of CORT had no effect on sex hormones perhaps
45 because CORT was low as a result of farming conditions that did not expose the animals to
46 severe or chronic stress.

47 **Keywords:** corticosterone; crocodile farming; crocodilians; estrogen; progesterone; sex
48 hormones; stress; testosterone.

49

50 **Resumen**

51 **Antecedentes:** La cría de cocodrilos en granja busca producir pieles de alta calidad de
52 cocodrilianos en cautiverio. El cautiverio usualmente expone a los animales a condiciones
53 estresantes, resultando en altas concentraciones séricas de corticosterona (CORT) que se
54 correlacionan negativamente con los niveles de hormonas sexuales y el éxito reproductivo.

55 **Objetivo:** Evaluar las concentraciones séricas de CORT y de hormonas sexuales y su

56 relación en cocodrilos *Moreletii* (*Crocodylus moreletii*) criados en granja, en la época no
57 reproductiva (NBS) y reproductiva (BS). **Métodos:** El estudio incluyó 59 cocodrilos adultos
58 (29 hembras y 30 machos). Se recolectó una muestra de sangre de cada cocodrilo en NBS
59 ($n = 31$) y BS ($n = 28$) para determinar las concentraciones séricas de CORT, estradiol (E_2),
60 progesterona (P_4) y testosterona (T). Durante el estudio, los cocodrilos permanecieron en
61 grupos mixtos de machos y hembras y fueron alimentados una o dos veces por semana.
62 **Resultados:** En hembras, CORT fue más alta ($p < 0.05$) en NBS, pero no se correlacionó
63 ($p > 0.05$) con E_2 o P_4 en ninguna temporada. En machos, CORT fue similar ($p > 0.05$) en
64 NBS y BS y no tuvo correlación ($p > 0.05$) con T. **Conclusión:** Las concentraciones de
65 CORT no tuvieron efecto sobre las hormonas sexuales tal vez porque la CORT fue baja
66 como resultado de condiciones de manejo de la granja que no expusieron a los animales a
67 estrés severo o crónico.
68 **Palabras clave:** *cocodrilianos; corticosterona; estrés; estrógenos; granja de cocodrilos;*

70

71 **Resumo**

72 **Antecedentes:** A criação de crocodilos em fazenda procura produzir couros de alta
73 qualidade de crocodilos em cativeiro. O cativeiro geralmente expõe os animais a condições
74 estressantes, resultando em altas concentrações de soro de corticosterona (CORT) que têm
75 correlação negativa com os níveis de hormônios sexuais e o sucesso reprodutivo. **Objetivo:**
76 Avaliar as concentrações de soro de CORT e hormônios sexuais e sua relação em crocodilos
77 *Moreletii* (*Crocodylus moreletii*) criado em fazenda, nas estações de não reprodução (NBS)
78 e reprodução (BS). **Métodos:** O estudo incluiu 59 crocodilos (29 fêmeas e 30 machos). Uma
79 amostra de sangue foi coletada de cada crocodilo em NBS ($n = 31$) e BS ($n = 28$) para
80 determinar as concentrações de soro de CORT, estradiol (E_2), progesterona (P_4) e
81 testosterona (T). Ao longo do estudo, os crocodilos permaneceram em grupos mistos de
82 machos e fêmeas e foram alimentados uma ou duas vezes por semana. **Resultados:** Em
83 fêmeas, CORT foi maior ($p < 0.05$) em NBS, mas não teve correlação ($p > 0.05$) com E_2 ou
84 P_4 em qualquer estação. Em machos, CORT foi parecido ($p > 0.05$) em NBS e BS e não teve
85 correlação ($p > 0.05$) com T. **Conclusão:** As concentrações de CORT não tiveram efeito

sobre os hormônios sexuais talvez porque o CORT foi baixo como resultado das condições de tratamento em fazenda que não expuseram os animais a estresse severo ou crônico.

Introduction

Crocodile farming commonly occurs under inappropriate management practices, which causes stress in the animals and a concurrent increase in plasma levels of corticosterone (CORT) (Isberg and Shilton, 2013; Finger *et al.*, 2015), which is the main glucocorticoid (GCs) in reptiles (Cockrem, 2013). While acute increases in GCs after short-term stressors are beneficial for the survival of the individual (Dantzer *et al.*, 2014), long-term increases in GCs after chronic stressors have deleterious effects on reproduction, immunity, and growth (Sapolsky *et al.*, 2000).

In farmed individuals, including crocodilians, chronic stress affects their health, reproduction, and productivity (Morici *et al.*, 1997), and high CT correlates negatively with concentrations of sex hormones and reproductive success (Lance and Elsey, 1986; Elsey *et al.*, 1991; 1994; Guillette *et al.*, 1995).

Data on the relationship between plasma CORT levels and sex hormones are available on the American alligator (*Alligator mississippiensis*; Lance and Elsey, 1986; Elsey *et al.*, 1990, 1991; Guillette *et al.*, 1997) and the Cuban crocodile (*Crocodylus rhombifer*; Augustine *et al.*, 2020). There is no information in this regard in Morelet's crocodile (*Crocodylus moreletii*). The Morelet's crocodile is native to Mexico and is included in Appendix II of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES, 2022). Hence, its legal use for conservation, research, or commercial purposes occurs in farms (Sánchez-Herrera *et al.*, 2011; Cedeño-Vázquez *et al.*, 2012), where crocodiles are housed usually in groups according to their size. However, the confinement of crocodiles increases their aggressive behavior, particularly in the breeding season, and leads to high levels of GCs (Elsey *et al.*, 1990; 1994).

117 Evaluation of CORT and sex hormones patterns in crocodilians can help monitor animal
118 welfare and reproductive status (Augustine *et al.*, 2020). The study hypothesized that CORT
119 correlated negatively with the levels of sex hormones in intensively managed Morelet's
120 crocodiles. Therefore, this study assessed the serum concentrations of CORT and sex
121 hormones and their relationship in farmed *C. moreletii* female and male adults during the
122 non-breeding (NBS) and breeding (BS) seasons.

123

124 **Materials and Methods**

125 *Ethical considerations*

126 Animal experimentation complied with the guidelines from the Bioethics and Animal
127 Welfare Commission of the School of Veterinary Medicine and Zootechnics of Universidad
128 Veracruzana (Act 07/22, November 24, 2022).

129

130 *Study characteristics*

131 The study was carried out in Veracruz, Mexico (Lat. 19°22' N, Long. 96°22' W) at the El
132 Colibrí de la Antigua crocodile farm. The study was conducted during two consecutive years
133 (2017–2019) to evaluate hormone concentrations in NBS (November) and BS (March). In
134 *C. moreletii* the breeding season starts in February or March with courtships and ends in
135 July with egg laying (Pérez-Higareda, 1980; Lazcano, 1982). During the study, mean annual
136 temperature and precipitation were 23.5 °C and 34 mm in NBS, and 26.7 °C and 15 mm in
137 BS.

138

139 *Experimental animals*

140 The study included 59 apparently healthy adult Morelet's crocodiles (≥ 1.51 m length, 29.2
141 ± 9.1 kg live weight; 29 females, 30 males). The crocodiles were randomly selected from
142 the general population of adult individuals that had reached commercial size. In NBS, blood
143 samples were collected from 31 individuals (15 females, 16 males), and in BS from 28 (14
144 females, 14 males). Different crocodiles were included in each evaluation to determine
145 hormone concentrations that could be representative of the population and not
146 concentrations in specific individuals. In addition, since the crocodiles had reached
147 commercial size, they were slaughtered a few days after sampling.

148

149 Crocodiles were housed in outdoor concrete enclosures with both females and males. Each
150 enclosure was 18 m length x 8 m breadth x 1.4 m height and had a pool of 17 x 6 x 1.4 m
151 filled with water at a depth of 80 cm, a basking area at each side, and a shaded area of 12 x
152 1.5 m. The stocking density was similar in both seasons of the year and it was 0.1 to 0.2
153 individuals/m².

154 Throughout the study, the crocodiles were fed a mixture of minced chicken and fish
155 elaborated at the farm (40% crude protein), at amounts of 10% of their live weight once or
156 twice a week. The food was spread throughout the basking area so each crocodile could get
157 some. They received mebendazole as a dewormer mixed with food every four months.

158

159 *Blood sample collection and processing*

160 Blood samples were collected to determine serum concentrations of CORT and sex
161 hormones (estradiol [E₂], progesterone [P₄], and testosterone [T]). For blood sample
162 collection, the crocodiles were captured from their enclosure one at a time. Once captured,
163 they were physically restrained and their snout taped shut to assure their own and the
164 handlers' safety. Their sex was determined and they were examined visually to exclude sick,
165 wounded, or emaciated individuals.

166

167 From each animal, one 3 to 5 mL blood sample was aseptically collected from the post-
168 occipital venous sinus within 3 min of capture (Romero and Reed, 2005), transferred into 6
169 mL plastic tubes without anticoagulant, and kept in a cooler for 1 to 2 h until the sampling
170 of all the individuals was completed. Then, blood samples were centrifuged at 810 x g for
171 10 min to obtain the serum, which was stored at -20 °C until hormone analysis. Blood
172 samples were collected once in NBS and once in BS in each year of the study, totaling four
173 blood samplings (November 2017/2018 and March 2018/2019).

174

175 After sampling, each crocodile was measured and weighed to determine its total length and
176 weight.

177

178 *Determination of serum hormone concentrations*

179 Serum concentrations of CORT were measured in both females and males, E₂ and P₄ in
180 females, and T in males, all by solid phase enzyme-linked immunosorbent assay (ELISA)
181 using commercial kits (DRG International, Inc., Springfield, NJ, USA). The hormone assays
182 were validated for crocodiles using one mammalian known sample as positive control in
183 each run of each hormone, to confirm that the assay detected the hormone and measured its
184 levels in crocodile serum. The validation values of the standard curves constructed to
185 calculate the results for each hormone were as follows: Corticosterone: R = 0.9891, Rsqr =
186 0.9881, Adj Rsqr: 9852, SE of estimate: 0.0279; Estradiol: R = 0.9987, Rsqr = 0.9974, Adj
187 Rsqr = 0.9949, SE of estimate = 0.0123; Progesterone: R = 0.9984, Rsqr = 0.9968, Adj Rsqr
188 = 0.9936, SE of estimate = 0.0085; Testosterone: R = 0.9990, Rsqr = 0.9980, Adj Rsqr =
189 0.9961, SE of estimate = 0.0512.

190

191 *Corticosterone.* The kit used was DRG[®] Corticosterone ELISA (DRG International, Inc.,
192 Springfield, NJ, USA). The assay indicated cross-reactivity with CORT (100%), P₄ (7.4%),
193 deoxycorticosterone (3.4%), 11-dehydrocorticosterone (1.6%) and cortisol (0.3%). The
194 assay range was 0 to 240 nmol/L and the sensitivity <1.6 nmol/L. The intra- and inter-assay
195 coefficients of variation (CV) were 3.1 and 6.0%. The resultant concentrations were
196 transformed from nmol/L into ng/mL by dividing them by 2.89.

197

198 *Estradiol.* The kit used was DRG[®] Estradiol ELISA (DRG International, Inc., Springfield,
199 NJ, USA). The assay indicated cross-reactivity with estradiol-17 β (100%), estrone (0.2%)
200 and estriol (0.05%). The assay range was 9.7 to 2,000 pg/mL and the sensitivity 9.7 pg/mL.
201 The intra- and inter-assay CV were 4.5 and 7.8%.

202

203 *Progesterone.* The kit used was DRG[®] Progesterone ELISA (DRG International, Inc.,
204 Springfield, NJ, USA). The assay indicated cross-reactivity with P₄ (100%), 11-
205 desoxycorticosterone (1.1%), pregnenolone (0.35%), 17 α -hydroxyprogesterone (0.3%) and
206 CORT (0.2%). The assay range was 0 to 40 ng/mL and the sensitivity 0.04 ng/mL. The
207 intra- and inter-assay CV were 6.4 and 6.6%.

208

209 *Testosterone*. The kit used was DRG® Testosterone ELISA (DRG International, Inc.,
 210 Springfield, NJ, USA). The assay indicated cross-reactivity with T (100%), 11β-
 211 hydroxytestosterone (3.3%), 19-nortestosterone (3.3%), androstenedione (0.9%) and 5α-
 212 dihydrotestosterone (0.8%). The assay range was 0.08 to 16 ng/mL and the sensitivity 0.08
 213 ng/mL. The intra- and inter-assay CV were 3.5 and 7.1%.

215 *Data analysis*

216 Differences in hormone concentrations between NBS and BS in females and males were
 217 analyzed with the Student's t-test for independent variables. A difference of $p < 0.05$ was
 218 considered significant. The Spearman's correlation coefficient was used to determine the
 219 relationship between the concentrations of CORT and E₂, P₄ and T. The tests were from
 220 Statistica 10® (StatSoft®, Inc., OK, USA).

222 **Results**

223 In females, concentrations of CORT and P₄ were higher ($p < 0.05$) in NBS, while levels of
 224 E₂ were similar ($p > 0.05$) in NBS and BS (Table 1). There was no correlation ($p > 0.05$)
 225 between concentrations of CORT and E₂ or P₄ in any season (Table 2).

227 In males, concentrations of CORT were similar ($p > 0.05$) in NBS and BS, while levels of T
 228 were higher ($p < 0.05$) in BS (Table 1). There was no correlation ($p > 0.05$) between
 229 concentrations of CORT and T in any season (Table 2).

231 **Table 1.** Serum concentrations (mean \pm SEM) of corticosterone and sex hormones in adult
 232 females and males of Morelet's crocodile (*Crocodylus moreletii*) in the non-breeding (NBS)
 233 and breeding (BS) seasons.

	NBS	BS
Females		
Corticosterone (ng/ml)	47.8 \pm 24.8 ^a	15.5 \pm 9.1 ^b
Estradiol (pg/ml)	203.0 \pm 110.2 ^a	251.6 \pm 191.4 ^a
Progesterone (ng/ml)	2.0 \pm 1.7 ^a	0.4 \pm 0.5 ^b
Males		

Corticosterone (ng/ml)	27.1 ± 17.5 ^a	23.4 ± 14.1 ^a
Testosterone (ng/ml)	2.3 ± 1.8 ^a	8.9 ± 5.1 ^b

Different superscript letters (^{a, b}) within rows indicate statistical difference by season (p<0.05).

Table 2. Correlation between serum concentrations of corticosterone and sex hormones in adult females and males of Morelet's crocodile (*Crocodylus moreletii*) in the non-breeding (NBS) and breeding (BS) seasons.

	NBS	BS
Females		
Corticosterone and estradiol	r = 0.02 p = 0.91	r = -0.47 p = 0.08
Corticosterone and progesterone	r = 0.35 p = 0.23	r = 0.65 p = 0.058
Males		
Corticosterone and testosterone	r = 0.24 p = 0.36	r = 0.16 p = 0.57

Discussion

Captive crocodilians will commonly experience some levels of stress (Elsey *et al.*, 1994), and in consequence, will have increased plasma CORT (Guillette *et al.*, 1995; Cockrem, 2013). In reptiles, CORT levels are usually higher in BS, when they might be necessary for reproduction (Tokarz and Summers, 2011). In this study, it was assumed that, because of farming conditions, crocodiles would be exposed to many stressors and show elevations in CORT, especially in BS because the demands of energy increase in such stage (Tokarz and Summers 2011), and that high CORT would decrease sex hormones levels. However, none of this occurred. Some explanations for these results could be that CORT was not high because the animals did not require a CORT release to mobilize energy during BS, similar to one report in male rattlesnake (*Crotalus atrox*; Taylor *et al.*, 2004), or that the management of the animals was adequate and thus they had low levels of stress, particularly the males, that showed similar CORT in NBS and BS. It has been reported that *C. moreletii*

254 does well in captivity and shows high tolerance towards conspecifics (Lang, 1987; Ojeda *et*
255 *al.*, 1998), which could contribute to low levels of stress and CORT. However, since there
256 are no reference values for CORT in *C. moreletii*, it is not possible to accurately know if the
257 levels found in the study could be considered as normal or if they were elevated, considering
258 that these are captive individuals.

259 Females had higher CORT in NBS, which could be a female response. Differences in CORT
260 levels are common in reptiles and result from variations, at individual or population level,
261 of the adrenocortical response to the same stressor caused by age, reproductive status, and
262 season of the year (Dunlap and Wingfield, 1995; Moore *et al.*, 2001; Moore and Jessop,
263 2003). However, as mentioned before, there are no reference values for CORT in *C.*
264 *moreletii* that allow to know if lower levels found in the study could be considered as normal
265 or if in both seasons CORT was indeed elevated. Therefore, it is necessary to conduct more
266 studies on captive *C. moreletii* to establish normal values of CORT in females and males to
267 help monitor the stress status throughout the year.

268
269 In females, the similarity in E₂ in NBS and BS was contrary to the expected, of higher E₂ in
270 BS. In tropical crocodilians, circulating E₂ increases in breeding females four to five months
271 before oviposition, as it stimulates vitellogenin production and growth of preovulatory
272 follicles (Uribe and Guillette, 2000; Calderón *et al.*, 2004; Milnes, 2011), and because the
273 oviduct grows during such time (Guillette *et al.*, 1997; Milnes, 2011). Thus, plasma E₂ is
274 elevated when vitellogenic follicles are present, namely, right before ovulation (Coutinho
275 *et al.*, 2000). The reason for not obtaining higher E₂ in BS could be that the timing and
276 number of samplings did not allow to detect the expected differences that should occur in
277 BS. The samples collected in March corresponded to the start of BS; hence, in March maybe
278 it was too early into BS to show elevated E₂. Thus, it is necessary to evaluate E₂ in adult
279 females several times throughout the year to establish normal values for different moments
280 within each season to determine the stage of the breeding cycle in which females are.

281
282 Serum P₄ levels were higher in NBS, contrary to what was expected and to the findings in
283 American alligator females indicating that plasma P₄ was barely detectable throughout the
284 year and only increased in the periovulatory period (Lance, 1989), and then declined after

285 oviposition (Guillette *et al.*, 1997). In Cuban crocodile (*Crocodylus rhombifer*) egg-laying
286 females, fecal P₄ metabolites were higher in the nesting season than in BS and NBS
287 (Augustine *et al.*, 2020), likely because P₄ promotes the formation and development of eggs
288 in reptiles (Custodia-Lora and Collard, 2002). In this study, P₄ was not evaluated in the
289 nesting season but at the start of BS, when the females were not close to ovulating yet. That
290 might be the reason for not observing differences in P₄ between NBS and BS. Hence, it is
291 necessary to evaluate P₄ at different moments within BS in adult females to establish normal
292 values for its different stages, including oviposition and nesting, to improve the
293 management of farmed females.

294

295 In this study, CORT did not correlate with E₂ and P₄. The lack of correlation between CORT
296 and E₂ was contrary to the negative correlation observed in female American alligators that
297 suggested that acute stress decreases E₂ levels (Elsey *et al.*, 1991). Exposure of females to
298 stressors can decrease E₂ levels in some reptiles (Elsey *et al.*, 1991; Ganesh and Yajurvedi,
299 2002), but the relationship between plasma CORT and E₂ or P₄ varies greatly with species
300 and reproductive state (Tokarz and Summers, 2011).

301

302 In males, higher levels of T in BS were expected and agreed with the results obtained in
303 American alligators (Lance, 1989; Guillette *et al.*, 1997) and Cuban crocodiles (Augustine
304 *et al.*, 2020), and with the reports indicating that in male crocodilians plasma T increases
305 concurrently with courtship and copulation, corresponding with the restart of gonadal
306 activity that begins four months before nesting, and that T declines abruptly at the end of
307 BS (Milnes, 2011). On the other hand, CORT had no correlation with T in NBS and BS,
308 contrary to the report that in male reptiles, T levels correlate positively with baseline CORT
309 (Eikenaar *et al.*, 2012). In male American alligators, CORT and T were negatively
310 correlated, indicating that CORT inhibits T secretion in males (Lance and Elsey, 1986).

311

312 In general, one explanation for the lack of correlation between CORT and E₂, P₄ or T in
313 NBS and BS in this study could be that CORT was not high enough to influence the levels
314 of sex hormones, suggesting that the crocodiles were not experiencing significant or chronic
315 stress in any season.

316

317 In conclusion, although CORT levels did not correlate to those of sex hormones in any sex
318 or season, suggesting that the management of the crocodiles was adequate for their well-
319 being and optimal reproduction, there were only two samplings throughout each year, which
320 might be insufficient to determine the effect of the husbandry practices on reproduction and
321 welfare. Therefore, it is necessary to conduct more studies on farmed *C. moreletii*
322 individuals at different times during NBS and BS to determine basal concentrations of
323 CORT and sex hormones, to learn accurately the effect of the management on their
324 reproduction and welfare, and to try to determine the optimal husbandry conditions for
325 captive Morelet's crocodiles.
